Mosca's inequality (x + y > z): x = 5, y = 3, z = 12 → time available under this scenario. z is a planning assumption chosen per risk profile, not a prediction. A cryptographically relevant quantum computer is not publicly known to exist today.

Post-quantum maturity: Level 0 of 4 — no post-quantum cryptography. Next step: Inventory where classical public-key cryptography protects long-lived data and keys, and choose the first migration: usually a hybrid TLS key exchange and wrapped keys.

Scope and boundaries

Mode: Document audit

Repository: https://github.com/zodl-inc/zodl-android @ 229dd3bff7490ea90ca4d7d79f3c539d71976f66 — evidence links open the lines at this commit.

Supplied inputs

1609 files, 6646108 bytes in total, 0 redaction(s); the per-file SHA-256 list is in appendix C.

Methodology

The audit was performed by the QSI engine 1.2.0. Each analyzer emits facts (rule, parameters, evidence); finding texts are generated from the rule catalog. Methodology sources are listed under "Sources and normative documents".

Prioritization uses an explainable weighted model (severity, exploitability, exposure, confidentiality/integrity/availability impact weighted by the "Small technology company" profile, asset criticality, urgency, ease of remediation) with a confidence multiplier. CVSS v3.1 is applied only to technical vulnerabilities with a defined vector. Long-term quantum risks use Mosca's inequality; their severity is capped at Medium and they are never presented as exploitable vulnerabilities.

Finding classes: confirmed technical vulnerability; known vulnerable component (a dependency version named in an advisory; whether the affected code is reachable is assessed separately, and a component confirmed by review becomes a vulnerability); confirmed configuration error; potential cryptographic risk; long-term post-quantum risk; improvement recommendation; insufficient data. Heuristic findings are marked preliminary; analyst decisions are shown next to the findings.

52 advisories in 16 development or build-only Maven package(s)

Improvement recommendation | Confidence: Medium | preliminary — requires further verification

OSV.dev lists 52 advisories (23 rated high or critical) for 16 Maven package(s) that only development or build tooling pulls in (build-conventions-secant/gradle.lockfile, buildSrc/buildscript-gradle.lockfile): e.g. com.google.guava:guava@33.3.1-android [build]: GHSA-xxph-c9ww-hj94; com.google.guava:guava@33.3.1-jre [build]: GHSA-xxph-c9ww-hj94; io.netty:netty-codec@4.1.110.Final [build]: GHSA-3p8m-j85q-pgmj, GHSA-558v-64gr-wgg4, GHSA-mj4r-2hfc-f8p6; io.netty:netty-codec-http@4.1.110.Final [build]: GHSA-38f8-5428-x5cv, GHSA-4mp9-239f-g9hg, GHSA-57rv-r2g8-2cj3, GHSA-6cqp-g7gg-8hr5, GHSA-6jqx-86gh-f27w, GHSA-84h7-rjj3-6jx4, GHSA-8c42-7qj2-3j46, GHSA-f6hv-jmp6-3vwv, GHSA-fghv-69vj-qj49, GHSA-gcjf-9mgh-3p7g, GHSA-hvcg-qmg6-jm4c, GHSA-jppx-w49h-x2qq, GHSA-m4cv-j2px-7723, GHSA-mvh2-crg5-v77c, GHSA-pwqr-wmgm-9rr8, GHSA-q4f6-jm68-57ww, GHSA-v8h7-rr48-vmmv, GHSA-xxqh-mfjm-7mv9; io.netty:netty-codec-http2@4.1.110.Final [build]: GHSA-563q-j3cm-6jxm, GHSA-5x3r-wrvg-rp6q, GHSA-93wv-jw9v-4972, GHSA-c2gf-v879-257j, GHSA-c69g-56f8-xwqj, GHSA-f6hv-jmp6-3vwv, GHSA-prj3-ccx8-p6x4, GHSA-w9fj-cfpg-grvv. The manifests mark them as such (devDependencies, "dev": true in package-lock.json, pnpm importers sections, [dev-dependencies]/[build-dependencies] reached through Cargo.lock, or — for yarn.lock, which records no scope at all — package.json reached through the lock graph), so they are not part of what ships.

Affected asset	dependencies:Maven:non-runtime
Data source	OSV.dev
Detection method	OSV.dev querybatch lookup of exact versions; scope from devDependencies, package-lock.json dev flags, pnpm importers sections, the Cargo.lock graph rooted at the Cargo.toml tables, and — for yarn.lock, which records no scope — the lock graph walked from package.json. Where a runtime requirement cannot be resolved in a lock, that lock is left unclassified rather than risking a package being set aside wrongly.

POTENTIAL IMPACT

They do not reach users of the product. They can affect developer machines and CI (supply chain): a compromised or vulnerable tool can tamper with builds.

LIMITATIONS OF THE CHECK

Advisory data comes from OSV.dev at the recorded time. Scopes come from the manifests; a registry crate's own build dependencies cannot be told apart in Cargo.lock, so the runtime set may be larger than reality, never smaller.

RECOMMENDATION

Update the tooling during routine maintenance; prioritise packages that run in CI with secrets or that produce release artefacts.

RETEST PROCEDURE

Re-run the dependency scan after updating.

Post-quantum assessment

Data/key lifetime x	5	5
Migration time y	3	3
Assumed years to CRQC z	12 (central)	12
x + y − z	-4 → time available under this scenario	-4 → time available under this scenario

No signature lifetime is set for the project; the data lifetime is used as an assumption.

Planning assumptions: x for key establishment, x for signatures, y are the defaults of the risk profile “Small technology company”, not the client's figures; with the client's actual lifetimes the verdict can change.

Post-quantum maturity: Level 0 of 4 — no post-quantum cryptography

Next step: Inventory where classical public-key cryptography protects long-lived data and keys, and choose the first migration: usually a hybrid TLS key exchange and wrapped keys.

Levels: 0 none; 1 present, not wired; 2 in use outside the critical paths; 3 hybrid in a critical path; 4 post-quantum by default in the critical paths (root of trust, key wrapping, channel key exchange). Judged from code and manifests.

z is a planning assumption chosen per risk profile, not a prediction. A cryptographically relevant quantum computer is not publicly known to exist today.

Quantum algorithms relevant to this inventory

Quantum algorithm	Effect	Inventoried algorithms (rows)	What it means for this audit

Grover's algorithm — key search and preimages Q1: quantum computation offline, classical access to the victim	weakens (larger keys restore the margin)	ChaCha20-Poly1305 (2), SHA-2 (1)	Not a break. 256-bit keys (AES-256, ChaCha20) keep a comfortable margin; AES-128 meets NIST category 1, while some authorities ask for 256-bit keys in quantum-resistant contexts (see the AES-128 entry). Prefer 256-bit keys for long-lived data; 256-bit hashes need no change for preimage resistance.
Brassard–Høyer–Tapp — collision search Q1: quantum computation offline, classical access to the victim	weakens (larger keys restore the margin)	SHA-2 (1)	256-bit hashes (SHA-256, SHA3-256) remain adequate for collision resistance; 160-bit hashes are already weak classically (SHA-1 collisions are practical). Use 384/512-bit hashes where NIST categories 4–5 are required.

Effects: breaks — replace the algorithm; weakens — larger keys or outputs restore the margin; included in standard parameters — no action at standard parameter sets; only with superposition queries — not applicable to ordinary deployments.

Limitations and assumptions

- z is a planning assumption chosen per risk profile, not a prediction. A cryptographically relevant quantum computer is not publicly known to exist today.
